Collection of forensically significant flying insects at the scene of surface deposited remains

Entomology

The collection and analyses of insects, or invertebrates, from crime scenes is generally well known among homicide investigators and death scene investigators. It has been the compiler's experience, however, that the actual practice of such collection, outside the presence of a forensic entomologist, is still overlooked or avoided. Often, an attitude prevails that that level of information is not necessary given the investigator's knowledge of when an abduction took place, or a subject's confession. In other situations, collections are not made simply because the investigators are not properly equipped with tools, chemicals, and packaging materials to collect and kill samples, or are not sure of what to do with, or how to store, live specimens. Entomological evidence is unique in that it is, in most criminal investigations, the only type of non-human evidence consisting of living, moving species. It is the hope of the compiler that this section will offer some answers toward appropriate collection procedures and equipment which are not expensive, do not involve a lot of time, or the need for additional manpower. The proper collection of entomological samples combined with accurate spatial, temporal, and environmental data, can yield valuable information toward determining postmortem intervals (**Taphonomy - Decomposition and Time Since Death**). Subject/Witness statements might be supported or disproved. Works such as Catts and Haskell (1990), and Lord and Burger (1983) have become standards in the field of forensic entomological procedures. In recent years compilations such as that by Byrd and Castner (2010) have demonstrated the increasing interest in forensic applications of a science which otherwise serves advancements in health and agriculture. Amendt, et al. (2007) offer "Standards and Guidelines" for this field of study. Entomology, as a means of determining post-mortem interval, continues to be scrutinized. This is not a bad thing. Any validation, clarification, or revocation of a forensic technique benefit crime scene interpretation.

Many of the works below include laboratory analyses and research. That research goes beyond

addressing the timing of a death or deposition (post-mortem interval) to toxicological determinations, interpretations of death scene versus depositional environments, *et cetera*. Like virtually every category in this bibliography, the study of entomology is contingent upon so many factors at a scene that an understanding of other disciplines is a necessity. Obviously, taphonomy and pathology are directly related to insect activity on discovered remains. Environmental characteristics such as soils and plants, as well as body position either by accident or intentional, could influence the impact of insects in peri- and post-mortem activity. Again, the reader is referred to other categories such as **Taphonomy, Geoarchaeology and Soil Science, and Criminal and Cultural Behavior**. (2342 citations)

Botany and Related Areas

Botanical or plant evidence is often overlooked at crime scenes. Unless plant remains such as seeds, or “burrs” are found adhering to the victim’s hair or remains, incidental to the collection of the body, independent control and questioned samples of plant parts “from leaf to root” are typically not recognized as evidence. Perhaps the standards of scientists such as Hall (1988, 1997), Willey and Heilman (1987), Warren (1975, 1980, 1984), or Bock and Norris (1997), will continue to alert investigators and prosecutors to the value of plant and plant component evidence. Compilations such as Miller Coyle’s Forensic Botany (2004) serve to reinforce and update developments in this critical component of crime scene analysis and reconstruction.

Forensic botany is a relatively young application of an old science. The majority of the references below address botanical and palynological collections and analyses as they relate to archaeological site deposits. For this reason, the researcher should also be aware of archaeological site reports under **Excavation and Recovery Strategies** which might contain information on site specific collections and analyses of plant remains. It has long been a standard in archaeology protocol to collect soil samples or “constant volume” samples for separation and identification of small plant remains. The use of this information by archaeologists to help interpret the climate and environment of sites during particular time periods, or to determine the diet of a site’s population have direct application to forensic settings. The same “answers” are often sought by crime scene investigators seeking to

validate subject or witness accounts, as well as time and location of death. A reflection of forensic botany's progression along with other forensic sciences is the increased number of resources addressing research and observations in plant DNA, (Bever, et al., [2002]; Linacre, et al., [2002]; Weising, et al., [2005]; and Craft, et al., [2007] to name a few.)

This bibliography's references in **Taphonomy** may also contain information/observations on the effect(s) of plant activity on disposed remains. Like entomological evidence, plant remains offer the opportunity to place remains or associated evidence in temporal and spatial contexts. Over time, plant growth may first serve to demarcate areas in which remains were disposed, and then impact the remains by utilizing them as a component of the lithosphere or biosphere. Botanical evidence also represents trace evidence which could link subject and victim and crime scene, as well as establish the movement of the subject and/or victim through a crime scene. From pollen to a rash from poison ivy, botanical clues follow Locard's principles of exchange. Trackers utilize damage to plants to find and follow paths taken by subjects and victims. The use and interpretation of botanical evidence requires holistic knowledge of crime scene environments, the accurate recording of same, and site specific conditions which might affect plant growth (see **Photography, Reconnaissance, Survey, and Mapping Techniques, Excavation and Recovery Strategies**, as well as **Geoarchaeology and Soil Science**).

Algology, Diatomology, and Limnology	1221
Mycology	1230
Palynology	1238
Botany, Phytology, and General Topics	1259

(Image Source: www.pixabay.com)

Algology, Diatomology, and Limnology

Accidental and intentional drowning cases routinely use diatomology to help to determine whether or not death by drowning has occurred and, if so, whether it occurred where the victim's body was found. Similarly, algae and other aquatic life, like terrestrial plants can be unique to a particular area. Their presence on, or in, a body can provide temporal and spatial clues of use in crime scene interpretation.

Mycology

Forensically, toxicologists routinely consider fungi as sources of hallucinogens or poisons. For the crime scene reconstructionist, mycological considerations are aligned more with Locard's exchange principle and disciplines related to taphonomy and geotaphonomy. As trace evidence, fungal spores may be transferred from the scene to subject and victim clothing, vehicles, weapons, et cetera. Fungal growth under and around surface deposited remains may offer clues to post-depositional interval. In situations where scavenging, or even subject relocation or dispersal of the body, has moved remains from their original disposal or concealment site, the presence of fungal growth may still mark that location. Cross-references with Geoarchaeology and Soils are obvious in the intimate relationship between fungi and soils.

Palynology

The largest sub-category of "Botany and Related Areas" in this bibliography deals with the study of pollen. That may be because of the ubiquitous nature of this plant component. That same characteristic makes pollen a useful trace evidence in connecting scenes, subjects and victims. With the primary and secondary transfer of hairs, fibers and dust between scenes comprising a criminal event, pollen may be used to develop linkages. Swabbing and taping of vehicle surfaces, clothing, and other substrates specifically for pollen evidence is rarely accomplished or even considered even though the resilient nature of pollen makes it a common source material for reconstructing even prehistoric site environments and activities. The other aspect of palynology which makes it less considered in crime scene processing is that its identification and interpretation requires the expertise of botanists or palynologists who are typically not forensically trained. Similarly, scientists such as entomologists or archaeologists normally do not work as crime scene specialists. What this indicates is that the relationships between law enforcement and non-law enforcement academically trained scientific specialists should be fostered.

Botany, Phytology, and General Topics

In addition to general references on botany, this last section includes some areas of botany less often considered by forensic practitioners. This compiler has used dendrochronology, the counting and analysis of growth rings, toward helping to determine the age of a clandestine burial. In that case, excavation revealed an approximately 10mm thick root growing across the top of a victim's skeletal remains. From a segment of that root collected from the scene, a University of Missouri botanist was able to determine that at least four years were required for it to have grown across the burial. Phytoliths, or the silica remains of certain plants are often used by archaeologists to explain age and context. The reader/researcher will also find below citations addressing the collection of plant evidence and archaeological site specific reports. The use of DNA and isotopes from plant materials are also increasingly used in archaeology and criminalistics. The reader is directed to references within this Bibliography contained in sections addressing DNA and isotope evidence.

Fingerprint, Footprint, Ear Print, Lip Print, Palate, Tattoo and Body Modification Evidence

In this edition of the Bibliography, references to "dermal impression evidence" have been separated from those discussing forms of body modification to include tattooing, piercing, branding, et cetera. Together these types of evidence form the most traditional bases of identification. Going back to Cesare Lombroso, Francis Galton, Alphonse Bertillon, et cetera, the use of personal features to define individual identification continues to develop or evolve. Most recently, the replacement, or enhancement, of the Integrated Automated Fingerprint Identification System (IAFIS) with "Next Generation Identification" (NGI) more than anything, demonstrates the need for wholism in forensic identification.

References such as Arp (2002), Ryder (1963), or Schmidt, et al. (1996) reveal connections between fingerprints and the archaeological record. Resources such as these also demonstrate the resilience of an otherwise fragile type of trace evidence. On more recent forensic archaeological sites, the importance and application of fingerprint technology should not be overlooked. Taphonomically, developments in the preservation and development of victim's fingerprints from tissue modified by mummification or submersion are continuous. Likewise, a suspect's fingerprints on the skin of a victim's body, is a topic discussed in several of the references listed below.

The ability to develop fingerprints on handled, or discarded, items around a crime scene is, dependent on understanding the environmental and chemical conditions which may have affected those prints as well as the substrates holding the friction ridge evidence. Once those conditions and the substrate are understood, the examiner can determine the appropriate techniques, and sequence of techniques, which can be used. The proper collection of fingerprint evidence also requires familiarity with other forensic examinations which may be conducted on the item. For example, the impact of fingerprint development methods on the integrity of DNA evidence is addressed in citations such as Andersen and Bramble (1997), Azoury, et al. (2002), or Schuetts-Henderson (1983). In this respect, the reader is best served to search for references in both this section and those on **DNA Evidence**, and **Blood and Body Fluids Evidence**.

This section also includes those citations which address other latent types of print evidence which might be found on a body or associated artifacts. Although less common, there have been instances where lip prints or ear prints have

linked suspects to a crime scene. As an example of how even these types of rare latent evidence can be cross-referenced to other categories in this bibliography, consider forensic research accomplished on the composition of lipstick (Rodger, et al. [1998] or Segui, et al. [2000] in **Trace and Impression Evidence**). Tattoos, and other body modifications, not only serve as means of identifying victims' remains, but also can indicate cultural or ritual affiliations. Again, the linkage between archaeological recovery and body modification evidence has become literal in the recovery of ancient mummified remains, or frozen in the case of Ötzi in the Italian Alps.

Dermal Impression Evidence	1291
Tattoo and Other Body Modifications	1474

Closeup of detail on the embalmed hand of a homicide victim exhumed for fingerprinting

Dermal Impression Evidence

One of the first realizations among criminal investigators is that fingerprint evidence does not often include finger prints. By that, I mean that it is more common to encounter the thenar areas of the hand, or ridge detail from the heel of a palm, or partial fingerprints, than the classic edge to edge rolled impression that is recorded on "ten print" cards upon arrest or some employment situations. For this reason, in criminal investigations, agencies try to collect "major case prints", also known as "full hand exemplars". Beyond the hands, unique detail from other body parts may be left at scenes or on objects of interest. This subsection includes miscellaneous works on dermal impression evidence, whether it entails the hands, feet, lips, ears or other body parts.

Tattoo and Other Body Modifications

Body modification evidence has been used routinely to help confirm the identity of human remains, as well as the living in security or surveillance footage. Not only the design, or culturally patterns, can be unique, but also signatures of the techniques used. Chemical composition of tattoo inks may also be attributed to particular shops or artists, who can then be contacted as witnesses in an investigation. The researcher interested in body modification evidence may find cross-references or associated topics under the sections of "**Criminal and Cultural Behavior**" and "**General and Cultural Anthropology of Death**".

Blood and Body Fluids Evidence

From an archaeological perspective, numerous resources regarding the retrieval of blood and other types of trace evidence from historic and prehistoric contexts are included in this category. The compiler wishes to reinforce that evidence exposed to the elements, or deposited years prior to discovery may retain significant information capable of impacting the interpretation of a crime scene. Both here and in the sections of **DNA Evidence** and **Stable Isotope Analyses**, several citations may be found which should demonstrate for the crime scene investigator that assumptions should never be made that blood and body fluid evidence is completely obliterated from older scenes. Loy and Wood, (1989), is an early example of how blood evidence remained viable over thousands of years. That approximately 9000 year old evidence from Cayonu Tepesi in Turkey was initially realized using one of the most basic presumptive test for blood in most crime scene technicians' tool boxes - Hemastix. Again, the section on **DNA Evidence** contains numerous citations expounding on work such as Loy and Wood. Analyses of prehistoric trace evidence is now common in archaeological and forensic literature.

A large part of this section deals with the reconstruction of violent crime scenes based on the shape, size, and position of blood spatter, or blood stain, evidence. Primarily considered at indoor crime scenes, the same type of reconstruction could apply to outdoor scenes but becomes more difficult given the effects of weather, and substrate movement. Works such as those of MacDonnell, (1997); Bevel and Gardner, (2001); and James, Kish, and Sutton, (2003), have served to expose criminal investigators to the stories represented in patterns of what would appear to most of us as bloody Rorshak tests. Those same works and others included in this section should also demonstrate the pitfalls of interpreting blood stain evidence without adequate training, experience, and certification.

Probably the the most cross-referenced citations in this section have to do with DNA research; however, the researcher is also directed to sections on **Photography, Fingerprint, Ear Print, Lip Print, and Tattoo Evidence, Firearms and Toolmark Evidence, Shoe and Tire Impression Evidence, and General Crime Scene and Death Scene Investigation Topics**, for techniques in recording blood pattern evidence and bloody transfers in form of patent and latent prints involving body and clothing segments.

This section is divided into the following categories:

Blood Stain Identification and Interpretation. 1491

Blood stains at the scene of a stabbing homicide

Blood Stain Identification and Interpretation

Part science, part art, and mostly dependant on empirical research and extensive experience in crime scene reconstruction and analyses, blood stain pattern analysis has become a standard in the reconstruction of violent scenes. Although the principles of fluid dynamics and trigonometry behind blood spatter analysis are straightforward, the contexts of the resultant stains are what require forensic specialists with years of experience in a variety of scenes. Bloodstain characteristics are for the most part related to traumatic injuries. There are obviously natural and accidental sources of patterns but the crime scene investigator is most drawn to those resulting from violence. For the same reason, those who consult this bibliography might be interested in Section III, **Taphonomy**, sub-sections referencing **Trauma**. Those sub-sections on **Photography** as well as **Surveying and Mapping** contain references of use toward the proper measurement of crime scenes and their features. Because Blood stains do not occur in chronological or spatial vacuums, knowledge of crime scene dynamics are key. For that the reader is directed to **General Crime Scene and Death Scene Investigations**. Even the sub-section **Entomology** is related to Blood Stain Pattern Analysis. Fly excrement and insect tracking through blood is often mistaken for blood spatter upon first glance.

Urine stains visualized using a forensic light source

Other Blood and Body Fluid Topics

Urine, sperm, vaginal fluid, and saliva are common in violent crime scenes. Unlike blood, however, the translucence or colorless nature, and relative lesser quantities, make it more difficult to recognize and therefore collect such stains without the applications of stains, dyes, and/or presumptive tests. This category in the bibliography includes references which address some of these methods as well as serological tests which are not in prior categories.

DNA Evidence

The topic of DNA is so thoroughly linked to forensic science, that it is assumed in almost every violent crimes case. A reflection of its ubiquity may be that this section of the bibliography contains the largest number of citations. This section primarily addresses human DNA; however; plant and non-human animal DNA are increasingly playing part in criminal investigations. Conservation Agents often use DNA to solve poaching cases, and plant DNA has been used to identify or link illicit drug evidence such as marijuana to scenes and suspects.

This is perhaps the single most cross-referenced category of the bibliography. One can understand why since almost every material at a crime scene may hold viable DNA evidence as a substrate or questioned sample. For example the soil in a grave from which a body was moved could contain decompositus bearing the victim's DNA; the thorns of a bush which scratched a subject while he disposed of a body could bear his DNA; biting insects have been found to contain viable amounts of DNA related to victims or suspects; and firearms might hold the DNA from the individual who gripped the gun while the barrel contains victim blood or tissue blown back toward the gun and suspect. This category also includes references which are, or could be included in that of **Geoarchaeology and Soil Science** or **Excavation and Recovery Strategies**. Many examples, such as Burger (2002) or Stone and Stoneking (1999) discuss the identification of ancient DNA in spite of the burial of the substrates or their exposure to the elements.

The refinement of DNA technology continues to require smaller and smaller amounts of material for examination. Likewise, age and contamination issues are addressed in many citations. Proper collection techniques are not only topics of some references below but also in general crime scene investigation references contained in **General Crime Scene and Death Scene Investigation Topics**.
