Introduction	vi

SECTION I: PREPARATION AND INITIAL ASSESSMENT

Planning, Reconnaissance, Surveys, and Mapping Techniques	0001
Safety	0002
Planning and Reconnaissance	0011
Surveying and Mapping	0035
Photography	0097
Aerial Photography and Photogrammetry	0098
Evidence Photography	0114
General and Miscellaneous Topics	0141
Canines and Scent Detection	0152
Geophysical/Remote Sensing Technology and Applications	0180
Ground Penetrating Radar	0181
Infrared and Thermal Techniques	0199
Magnetometry and Metal Detection	0204
Remote Sensing Technologies	0220
Hyperspectral Imaging Technologies	0246
Miscellaneous Techniques and General Topics	0251

SECTION II: RECOVERY AND SETTING

Excavation and Recovery Strategies	0292
Geoarchaeology and Soil Science	0372

SECTION III: TAPHONOMY

Introduction	0471
Decomposition and Time Since Death	0472
Disease, Illness and Physical Abnormalities	0588
Thermal Alteration or Influences	0652
Cold Environments	0653
Hot Environments	0662
Scavenging, Animal Attacks, Faunalurbation, and Bitemark Evidence	0706
Scavenging, Animal Bites, and Faunalurbation	0707

Human Bitemark Evidence	0750
Trauma	0778
Edged, Incised, Hacking and Impaling Traumas	0779
Blunt, Fracture, and Crushing Traumas	0829
Hangings, Asphyxial Injuries and the Use of Ligatures	0893
Ballistic Wounds	0923
Miscellaneous, General, and Other Traumas	0987
General and Miscellaneous Topics Related to Taphonomy	1048
SECTION IV: ENVIRONMENTAL EVIDENCE	
Entomology	1101
Botany and Related Areas	1221
Algology, Diatomology, and Limnology	1222
Mycology	1231
Palynology	1239
Botany, Phytology, and General Topics	1260
SECTION V: MISCELLANEOUS EVIDENCE	
Finger, Foot, Ear, Lip Print, Palate, and Body Modification Evidence	1290
Dermal Impression Evidence	1291
Tattoo and Other Body Modifications	1474
Blood and Body Fluids Evidence	1490
Blood Stain Identification and Interpretation	1491
Other Blood and Body Fluids Topics	1573
DNA Evidence	1612
Isotopic Evidence	1913
Firearms, Projectiles, and Tool Mark Evidence	2001
Firearms and Ballistics Evidence	2002
General Tool Mark Evidence	2106
Miscellaneous Trace Evidence	2129
Fecal and Coprolite Evidence	2130
Hair and Feather Evidence	2138
Fiber and Textile Evidence	2177
Other Trace Evidence Topics	2208
Shoe, Foot, and Tire Impression Evidence	2257

SECTION VI: INVESTIGATION, BACKGROUND, AND TRIAL

Mass Fatality and Human Rights Investigations	2305
Air Disasters	2306
Mass Graves and Conflict Archaeology	2320
Other Mass Fatalities and General Topics	2357
General and Cultural Anthropology of Death	2414
Criminal and Cultural Behavior	2468
General Crime Scene and Death Scene Investigation	2602
Nonfiction Accounts of Buried Body Cases	2723
Expert Testimony and Ethical Conduct	2739
Related Web Sites	2800
Response, Investigative, Regulatory, and Crisis Management Agencies ..	2801
General Forensic Science Resources	2804

Forensic Entomology	2808
Other Helpful Sites	2809

Acknowledgments

As with all prior editions of this bibliography, my deepest appreciation goes to colleagues, friends and family who continue to provide support and input. Beginning with the twelfth edition I promised that I would always dedicate this bibliography to one of its biggest supporters. Anthony Meadows passed from this world on March 24, 2005. Tony was a Marine and a Disabled Veteran who took the dedication, honor, and pride he had in his military experience and applied it to his work as an Information Technology Assistant for the Federal Bureau of Investigation's St. Louis Division. Tony never hesitated to help me with what must have seemed my endless questions about software or computers. He helped to develop spreadsheets and other programs for different research projects. Even after I transferred from Missouri to Pennsylvania, Tony said it was an honor when I would send him cds and he would copy each year's bibliography as well as print the labels for each cd. I know I am not the only agent or support person who appreciated Tony's willingness to help in what ever way he could, in spite of chronic pain from an injury he received in Vietnam which took his leg and required endless surgeries. Tony will always be remembered for his expertise, enthusiasm, support, personality, heart, and so much more. This bibliography will forever miss his touch, but will forever be dedicated to his memory. Thank you, Tony.

2016 A Bibliography Related to Crime Scene Interpretation with Emphases in Geotaphonomic and Forensic Archaeological Field Techniques, Eighteenth Edition. Published by the author, Johnstown, Pennsylvania.

(Cover designed by compiler)

Introduction

The following bibliography consists of resources that contain information related to the recovery of crime scene evidence in outdoor contexts. One discipline which inherently involves the collection, recording and examination of outdoor environmental data is archaeology. In practice, archaeology and criminalistics share the goal of systematically documenting, collecting and interpreting physical evidence for the purpose of understanding the depositional history of that evidence. The goals of forensic science in general and archaeology specifically, are similar in many ways. This is evident in their respective definitions. Archaeology may be defined as “the systematic recovery by scientific methods of material evidence remaining from man’s life and culture in past ages, and the detailed study of this evidence” (American Heritage Dictionary, 1978:67). If the temporal references in this definition are removed it becomes interchangeable with broader definitions of “forensic science”.

The most often addressed topic in forensic science literature is that of homicide. As Geberth (2005:1) begins, "The homicide crime scene is, without a doubt, the most important crime scene to which a police officer or investigator will be called upon to respond." The same can be said for forensic specialists including forensic archaeologists. Forensic archaeology is almost exclusively thought associated with the recovery of buried homicide victims. It is hoped, however, that this bibliography causes the reader to consider the variety of evidence which might be found below and above ground at any scene, and especially those outdoor. The investigator or researcher should also consider that crime scene burials do not always involve matrices of soil, just as they are not limited to concealing human remains. When the crime scene is located outdoors the potentially vast number of extrinsic factors (such as geological, environmental, plant and animal disturbances) can lead to a sense of futility in fully documenting and ultimately interpreting the evidence and scene. Forensic archaeologists, unlike most crime scene experts, focus upon the collection of a plethora of evidence in order to reconstruct events of the, very often, distant past. Standard documentation procedures in the archaeological investigation of a site/scene include descriptions of the physical setting, climatic setting, botanical remains, entomological remains, architectural features, and the relationship of all of the physical evidence to the entire contextual setting. These details are documented via written notes, photographic and videographic images as well as the production of detailed maps of the spatial distribution of evidence relative to topographic and other features of the setting.

In an attempt to bring archaeological methods out of entirely subterranean contexts, this bibliography includes resources which contain information applicable to most crime scene settings. For example, mapping protocols developed by archaeologists for data collection in confined spaces such as rockshelters or caves, have direct use indoors at scenes requiring precision documentation of ballistic, blood spatter, and other positional evidence. Electronic total station technology used in surveying and archaeology since the 1970s has been cited as the state of the art in crime scene mapping. Geophysical prospection for historic and prehistoric features is now one of the first considerations in the search for buried evidence. Published methodologies for collecting and analyzing residual blood evidence from artifacts more than

10,000 years old have been in practice for more than twenty years. Techniques of trace evidence analyses have evolved throughout the formal history of archaeological science. Some of the most recent contributions continue to help link artifacts with their genetic or manufactured origins. Several of the listed sources may not discuss excavation techniques per se but are related in their discussions of mortuary practices, photography, mapping procedures, geological and pedological studies, geophysical sensing applications, and environmental parameters affecting entomological, botanical and taphonomic research.

The 2016 printing of this bibliography contains over 53,000 citations. An attempt has been made to group references in one of sixty eight sections and subsections organized in much the way an investigator might logically approach the search for, and processing of, a violent crime scene. The topics continue beyond the crime scene; however, and take the investigator to analytical, cultural, and theoretical views of cases, behavior, and evidence. The section of **Expert Testimony and Ethical Conduct** represents the culmination of the investigator's work in the presentation of the facts in a court of law. To that point, this journey from planning to presentation is reflected in the following categories, or sections: **Planning, Reconnaissance, Surveys, and Mapping Techniques; Photography; Canines and Scent Detection; Geophysical/Remote Sensing Technology and Applications; Excavation and Recovery Strategies; Geoarchaeology and Soil Science; Taphonomy; Entomology; Botany and Related Areas; Finger, Foot, Ear, Lip Print, Palate and Body Modification Evidence; Blood and Body Fluids Evidence; DNA Evidence; Isotopic Evidence; Firearms, Projectiles and Tool Mark Evidence; Miscellaneous Trace Evidence; Shoe, Foot and Tire Impression Evidence; General and Cultural Anthropology of Death; Criminal and Cultural Behavior; General Crime Scene and Death Scene Investigation; and Nonfiction Accounts. Mass Fatality and Human Rights Investigations** was added in previous editions to reflect the increased service of forensic scientists, and especially archaeologists as a result of international human rights atrocities, and increased terrorism. The final section entitled **Related Web Sites** offers a few additional resources on a variety of disciplines.

In an effort to make the bibliography more "user friendly" several sections contain subcategories. For example, references in the **Taphonomy** section are categorized under "Decomposition and Time Since Death", "Thermal Alteration", "Scavenging", et cetera. References were also reviewed for redundancy in order to make the compilation more concise. The compiler has attempted to place articles in those sections/subcategories which seem to most directly reflect the content of the article as represented by its title. There are, however, citations which might apply to one or more categories. For example, " Using Alginate Gel Followed by Chemical Enhancement to Recover Blood-Contaminated Fingermarks from Fabrics" by Bentolila, et al. (2016) has been categorized under "**Finger, Foot Ear, Lip Print, ...**", "**Blood and Body Fluids Evidence**", and "**Shoe, Foot and Tire Impression Evidence**", and could also have been included under the Fibers and Textile sub-section of the **Miscellaneous Trace Evidence** category. Similarly, the article "The Dirty Dozen: The Recognition and Collection of Tool Marks in the Forensic Geotaphonomic Record", by the compiler (1997) contains observations and discussion of geoarchaeology, archaeological techniques, and search logistics. It was placed

in the "General Tool Mark" category of **Firearms, Projectiles and Tool Mark Evidence** because it most directly addressed the collection of tool marks as trace evidence left behind at buried crime scenes. In an effort to avoid redundancy most citations are only mentioned once and not cross-referenced between sections. Therefore, readers are encouraged to explore categories outside those which might seem to contain more obvious citations in the topic being researched. There are a few citations which were so evenly divided in the nature of their topic that they are contained in two different sections. For example, "The Effects of Fingerprint Enhancement Light Sources on Subsequent PCR-STR DNA Analysis of Fresh Bloodstains" by Andersen and Bramble (1997) appears in **Fingerprint, Footprint, Ear Print, Lip Print and Tattoo or Other Body Modification Evidence** as well as **DNA Evidence**.

This bibliography is not annotated or intended as a review of the compiled citations. Many of the citations are included because they are cited in more primary resources and, by caption or abstract, appear to offer information relative to forensic science in general and archaeological/geotaphonomic theory and practice specifically. It is left to the reader to determine of what value each reference might be to their own research, or whether the research documented within any given citation is sound. Many citations are of earlier vintage. Although some of these earlier articles, especially in technical areas such as photography, geophysical exploration or mapping, might seem outdated; many contain information on basic, immutable, technological principles of any age. Also, the inclusion of older resources allows the reader an opportunity to examine the evolution of concepts and techniques in particular areas.

References strictly concerned with osteological, odontological, and physical anthropological analyses of human remains, toward determinations of sex, race, age, and stature, are not included in this edition. (The exceptions are a few field guides which represent basic aids for gross field identifications.) Articles which contain information on taphonomy, or the use of physical anthropology and forensic pathology to determine the ante-, peri-, and postmortem history of remains, are included. Occasional prehistoric and historic archaeological reports are also included. They not only document excavation techniques, but are also included for the information they provide concerning the cultural and temporal diversities of mortuary practices. Non-fiction accounts of well known homicide investigations are referenced. Such accounts may not offer analytical or scientific views; however, they do present the reported circumstances surrounding high profile buried body investigations. These non-fiction accounts may also offer some insight into the application, or lack, of forensic archaeology and geotaphonomy in homicide investigations where evidence was buried.

This bibliography is by no means exhaustive. Beyond the exclusion of strict physical anthropological, odontological, and osteological references, there are innumerable archaeological field reports which address the sampling and excavation of interment sites. Each day newspapers and magazines across the world include articles about the discovery of human remains in forensic and non-forensic situations. As with all science, research in archaeological field techniques, taphonomy, entomology, botany, criminalistics, and each of the represented disciplines are not static. As they become available to the writer, applicable citations will be added to this bibliography, and any suggestions are appreciated.

Images used throughout this bibliography are those of the authors unless the image source is cited. Of those images which are gleaned from the Internet, they do not represent an endorsement of the source product, program, agency or company. Rather, they offer visual examples of the categories to follow and respites from pages and pages of text.

This bibliography is offered at no cost. It was developed as an aid for students, civilian and law enforcement, interested in crime scene investigation. It is hoped that this bibliography will be copied and provided to colleagues, students, and peers. If additional copies are needed, please contact me and I will be happy to send copies.

Planning, Reconnaissance, Surveys, and Mapping Techniques

After it is secured, the first step toward processing a crime scene is assessing and recording its position *in situ* as well as its relationship to other sites affected by subject(s) and victim(s). This follows tenets shared by archaeology, geotaphonomy, and general criminalistics: Crime scenes do not occur in vacuums. They entail points of access, egress, and are influenced by immediate and neighboring environmental activities. Consider cases in which lone skulls are found by pedestrians. More often than not, those skulls were once attached to remains which lie nearby. By recording the environment or context from which the skull was recovered, (beyond its mere two dimensional position within a small grid), its peri- and postmortem history may become more clear. The routine recording of elevations and topographic features such as streams, flood plains, slopes, *et cetera*, near remains could provide the investigator, laboratory analyst, and ultimately a jury, with information related to taphonomic processes affecting those remains and explanations for their ultimate dispositions. Too often investigators take a myopic view toward crime scenes and concentrate only on the area around the primary piece of evidence. The experienced, well-trained, and practiced crime scene investigator or archaeologist realizes three integrated and expanding spheres of any investigation: the evidence or artifact, the incident, and the event. Toward expanding perspective into the incident and event spheres of investigation, this category contains resources which generally entail topics of search or survey techniques as well as mapping methodologies and equipment. Several of the articles also apply to logistics and preparation; however, the reader is also directed to the categories of “**General Crime Scene and Death Scene Investigation**” and “**Excavation and Recovery Strategies**” for additional references which contain discussions about logistics and planning.

The most important component of planning for a forensic search or recovery is consideration of personal and team safety. Many sites suitable for the disposal of homicide victims pose significant risks to living individuals. Sites such as landfills and cesspools demonstrate one type of obvious hazard, while confined spaces such as wells, cisterns, or mine shafts represent another with less visible dangers such as carbon monoxide or structural collapse. Attention to safety extends beyond the field to laboratory and storage settings. Inadequate facilities, personal protection, or inappropriate handling of hazardous evidence or chemicals used to process evidence can put technicians and scientists at significant risk. For these reasons, this section of the bibliography begins with the topic of safety.

This section is divided into the following categories:

Safety	002
Planning and Reconnaissance	011

FBI ERT "suit-up" in protective gear before entering the scene of a double homicide

Safety

As investigators, of either prehistoric and historic circumstances or contemporary criminal situations, we tend to put the goal of solution as our priority. The archaeologist, in an academic situation, is more likely to recognize that risking ones health or safety is not worth a particular discovery, whereas the law enforcement officer tends to balance risk in the life and death circumstances of a case with that of his job. There is an often overlooked adage that, as investigators, we do not want to become part of the problem – meaning that endangering our own lives only adds to the victims of a particular crime. In spite of such warnings from supervisors and colleagues, investigators will probably continue to overlook their own safety in place of pursuing the "bad guys", and justice for their victims . . . especially in matters involving homicide or personal violence. Perhaps that tendency is, in part, due to a lack of understanding of the long term dangers involved. If cancer, emphysema, silicosis, et cetera, could be felt at the moment their agents entered our bodies, like the heat from aflame or pain of a fracture, crime scene responders would not hesitate to immediately use safety equipment afforded to them. Many of the articles included below detail such inherent dangers and approaches toward minimizing same.

Planning and Reconnaissance

It is not often that crime scene technicians and detectives have the luxury of preparing for the search and recovery of victims or crime scene evidence. In most situations, they are notified of the discovery of human remains by hunters, farmers, or other pedestrians, and respond immediately. The compiler's own review of buried body cases as reported in newspapers, (Hochrein, 1999), and as cited below, found formal law enforcement searches as one of the least likely means by which clandestine graves were located. The Internet offers crime scene investigators so much data on the sites they will process that there are few excuses for one not to have site familiarity before they arrive on scene. Aerial imagery, topographic remains, hydrology, soil surveys, et cetera, can be downloaded to a smartphone on the way to a scene if need be. Such background not only helps in response logistics and safety, but it also provides insight into the setting and terrain in which subject(s) had to have navigated. The articles included in this sub-section are offered for consideration for those investigators who wish not only to personally prepare themselves, but also wish to cross-train with experts in other disciplines toward approaching the crime scene prepared and with the appropriate expertise and tools at hand. Readers or researchers interested in this sub-section of the bibliography should also look through **Canines and Scent Detection** as well as **Geophysical/ Remote Sensing Technology and Applications**, which include methods which should be discussed in the planning and reconnaissance before searches for concealed evidence

Surveying and Mapping

One of the most tedious parts of any forensic search and recovery exercise involves the collection of measurements in order to create a two or three dimensional scaled diagram of the scene. Acquiring those measurements does not typically entail the relative ease and speed of photography. Yet the images they produce, if done accurately, are truer representations of size and orientation than those recorded via photographs. Obviously, photography is absolutely essential while processing a crime scene. One must remember, however, that the interpretation of any photograph is affected by the angle or view at which it was taken, lighting conditions, lens choices, and depth of field. A map or diagram done properly, with attention paid to detail, can be used in concert with photographs to present a complete and contextually accurate representation of a crime scene. When mapping is absent, incomplete, or inaccurate, investigations may be opened to suggestions that features of the scene were fabricated or intentionally ignored. Since this bibliography's first edition, the state of the art of forensic mapping has become more sophisticated. Electronic distance measurers in the form of handheld devices and total stations are routinely seen at major crime scenes or disaster settings. Three Dimensional scanning has become more cost effective for smaller departments. Now, instead of hundreds points of data collected at a single scene, millions are collected in a matter of minutes. More data equates to more opportunity for objective reconstruction and analysis.

Many cases remain open for years and may pass from investigator to investigator. Good diagrams can be the basis for acquainting, or reacquainting, investigators, witnesses, forensic experts, jurists and jurors with the most accurate reconstruction of a scene that may have long disappeared. In other cases where a site is processed multiple times as information develops over the years, mapping surveys allow all the evidence from each of the searches/recoveries to be linked in a common diagram. Measurements taken in three dimensions allow for the creation of models and profiles which depict the crime scene terrain in ways not possible through photographic views or flat, two dimensional, drawings. This may be critical for a forensic analyst trying to determine why evidence was

found in certain positions, or for courtroom presentations seeking to establish eyewitness views. The position of a single tree, or bush, may significantly impact eyewitness testimony depending on whether it could have obstructed his or her view. Or consider the recovery of skeletal remains in which the skull is found several meters away from the rest of the body. A three dimensional depiction recording the skull at the bottom of a steep hill could immediately offer the pathologist or other laboratory analyst a possible explanation for the disarticulated remains whereas a two dimensional drawing might not be as explicit.

The updated bibliography includes citations dating from 1873 to 2015. These references to surveying techniques, over decades, allow the investigator, trainer and student to understand the evolution of modern mapping systems. By knowing the bases, or underlying principles which govern modern computerized instrumentation, the crime scene surveyor becomes more than an operator pushing buttons on a machine. He understands what the machine is doing and can respond when equipment malfunction. He is better prepared to explain techniques to fellow investigators and more confidently testify in court about the evidence collection methods used.

Photography and Imaging

Perhaps no aspect of crime scene documentation is more important and more demonstrable than photography. The mere press of a button can lock in time a theoretically unbiased account of a scene or subject. How often have we experienced, or heard of, cases successfully resolved and adjudicated with the inclusion of accurate and complete photographs? Most investigators have also experienced the opposite situation in which too few, or poor quality photographs are taken of a scene. For the analyst, jurist and jury person who have not had the opportunity to be at the crime scene as it was found by the investigator, photographs or videos may be the only remaining means of observing the condition of remains and environmental factors which may have affected their state. Most forensic anthropologists can relate personal horror stories of remains brought or shipped to their laboratories with little or no contextual record. Photographs of the original position of remains in their discovered context at the scene can be invaluable in such situations. An often used adage in police investigations is “film is cheap,” meaning that one can never take too many pictures of the crime scene, its contents, and its environs. Digital photographic technology advances each year with the increased ability to take more and better detailed pictures using adequate equipment affordable to most law enforcement. Smartphones now have cameras with more pixel capacity than some sole-functioning cameras.

It is inexcusable for investigators to leave a crime scene without a good photographic record. Having said that, investigators must also realize that photography is but one part of a documentation trilogy. Accurate crime scene reconstruction is best served by incorporating good photography with good diagramming or mapping, and good note taking. The three not only act as checks on the others, but also fill each other's shortcomings. For example, photographs represent a perspective and can be affected by things such as parallax. Diagrams are limited by their schematic nature; notes by their lack of visual depictions. In concert, this trilogy of documentation techniques most completely preserves and describes a scene that is temporary in time and space.

This bibliography devotes an entire category to photography and photogrammetry - The art or process of surveying or mapping via photographs, and usually aerial photographs. Several references to photogrammetric mapping may also be found in “**Planning, Reconnaissance, Surveys, and Mapping Techniques**”. This section of the bibliography may also include occasional references to remote sensing and satellite imagery as they utilize photogrammetry. Those citations may be cross-referenced to the section on **Geophysical/Remote Sensing Technology and Applications**. For more sources related to remote sensing, the reader is directed to that section.

This section is divided into the following categories:

Aerial Photography and Photogrammetry	0098
Evidence Photography	0114
General and Miscellaneous Topics	0141

(Image Source: www.pixabay.com)

Aerial Photography and Photogrammetry

Aerial platforms for photography serve a variety of purposes throughout an investigation. At the outset, features not visible at elevation are often revealed at altitude. For example the subtle depressed areas of clandestine pits may be exposed in aerial photographs as shadows during the early morning or late afternoon are their longest. Another search technique involving aerial photography involves the comparison of historical aerial images in an attempt to discover buildings, gardens, or other features placed over buried evidence to conceal same. During an investigation, aerial photographs can serve as interview aides to help witnesses relate locations involved in an incident, or to gauge a subject's reaction to certain locations at a crime scene. In the prosecutive phase of a case, one of the first ways a jury is acquainted with an outdoor crime scene is through aerial photographs. Technologically, the use of unmanned aerial vehicles, (UAVs), or "drones" are increasingly in the news. Small portable UAVs, with appropriate air space clearances when needed, can be hovered over outdoor and even indoor crime scenes to acquire video and still photographs. This additional perspective, again, enhances documentation and interpretation of each scene.

Photogrammetry is defined as the science of making measurements from the details captured in photographs. It is based on perspective and projective geometry. Because, however, it is inherently photography, this topic is

included in this general section and more specifically in the subcategory including aerial photography because it has historically been most associated with large area surveys. Even by its simplest definition, this science could be as easily categorized under **Surveying and Mapping** as **Photography**. Likewise, it also falls into the realm of remote sensing technologies as a geospatial technology, (Konecny, 2014). The American Society of Photogrammetry and Remote Sensing was founded in 1934 to advance such technological developments. Arguably, photogrammetry is more often accomplished from aerial platforms toward the production of stereo plotted images of large areas. This allows an interpretation of depths and elevations in what would otherwise appear as a two dimensional landscape. For the crime scene investigator, understanding the topography of a search area is extremely helpful logistically and for understanding and limiting areas to be searched. Forensically, photogrammetry is most often used from terrestrial platforms where standard photographs, at different angles, and sometimes incorporating targets or reference placards are subject photogrammetry software which digitally extracts the distances between objects and surfaces. Gonzalez-Aquilera and Gomez-Lahoz (2009) offer descriptions and explanations of the application of photogrammetry to crime scenes in general.

As the name implies, close-range photogrammetry, or image based modelling, requires the camera placement closer to the objects of interest, ie. the interior of a room associated with a homicide incident, or individual artifacts from an excavation. Today, the principles of close-range photogrammetry are reflected in crime scene scans, 3D printing, virtual courtroom exhibits, GIS products, et cetera.

Evidence Photography

Although not the only form of documentation which should be used at crime scenes, photography is the first to be considered. Like any technology, the state of the art in photography advances at a rapid pace. Today, digital cameras have replaced film formats while the nature of the digital technology advances even further. There are few excuses for not documenting the crime scene photographically. At a minimum, the ubiquitous nature of smartphones allows any investigator access to high resolution photography in lieu of, or while, waiting for crime scene technicians to arrive at a scene. The concern is the security or evidentiary control of those images. Photographic images of scenes and evidence now also serve to provide a basis for measurement. As mentioned above, the science of photogrammetry, (**Aerial Photography and Photogrammetry** in this section of the Bibliography), is applied to determine distances from photographs. Spherical photography and 360 degree videography are used increasingly to record the scene in a manner which allows juries to virtually step inside the scene. The compiler has found these techniques especially helpful in documenting subject routes to, or from, scenes; and to allow juries to better experience settings which they cannot tour, such as the interior of a prison. The citations in this section reflect both the evolution of photography but also the advantages and pitfalls of a diverse technology and its forensic applications.

General and Miscellaneous Topics

The remainder of the citations in this section of the Bibliography entail general theory and techniques in photography, processing, as well as film and filter types. A general bibliography on photography would require volumes. These citations are those, general in nature, gleaned as references in forensic science articles or texts. (225 citations)

Canines and Scent Detection

The topic of search dogs could be a component of a more all-encompassing category of search techniques. It is highlighted here, however, because of the routine historic use of dogs in searches for both live and deceased victims. The compiler has found the use of qualified cadaver dog teams the most efficient and cost effective means of searching large areas. By the same token, he has been frustrated by the inconsistency of some dogs and the inappropriate conduct by their handlers. Search and rescue teams will typically volunteer their efforts. A canine search is inherently a low impact technique involving minimal disruption of potential buried scenes. It is also a technique which can be implemented discretely and repeatedly as environmental conditions (ie. temperature, moisture, or vegetation), change across a search area. A drawback to the use of dogs involves confirmation of their abilities. Obviously, the best confirmation includes a history of multiple finds in the past. In the absence of such history and referrals, the nature and extent of the team’s training should be considered. The resources listed below should offer insight into proper training techniques and the use of canine search teams. The use of trained canines is only one of several search tools. The competent investigator incorporates as many tools as feasible yet does not base his investigation on one technique or resource.

An important aspect of incorporating a qualified search dog team into a law enforcement investigation is preparation through cross-training. While a member of the FBI’s St. Louis Evidence Response Team, the compiler introduced outside cadaver dogs and handlers into Evidence Response Team training as a way to familiarize both teams with the capabilities and protocols of the other. Periodic testing of dogs and their handlers is a must. Search dog handlers reluctant to be tested using accepted training standards should be avoided. Likewise, investigators should not be shy in requesting documentation of finds and failed searches by search teams under consideration.

Legitimate teams record those call-outs they have had and the results of same. If they do not, or only document finds without recording later discoveries missed by their dogs, then they should be avoided. As a crime scene investigator, the compiler considers legitimate those handlers who acknowledge failed searches, among their successes, in which victims' remains were missed by their dogs. Those handlers have then analyzed such experiences to determine why their dogs did not alert and to refine their training.

Consideration of search dogs should also include the conduct of their handlers. Their backgrounds, behavior, and ethics will be scrutinized in court if not by the law enforcement who use them. In 2005, internationally recognized dog handler Sandy Anderson was convicted after an investigation discovered her planting of human remains fragments at search sites. (Shepardson, 2004 and Walker, 2004 below). Unfortunately, Anderson's canine counterpart, "Eagle", had successfully located victims. This handler's unethical behavior was not necessary to enhance or validate the capabilities of her dog.

As with virtually every other category in this bibliography, technological developments attempt to improve the state of the art. Vass, et al's. (2004 through 2012) work, and others in scent detection, seek to develop devices which may never replace man's best friend, but to join him as another tool in the search arsenal. With mass disasters such as the aftermath of September 11, 2001 and Hurricane Katrina in 2005, research into scent measurements is increasingly appearing in mass media and forensic science literature. Citations encountered by the compiler are included in this section. The reader is also directed to that section of this bibliography which deals with topics of Decomposition under **Taphonomy**.

Infrared Thermography (IRT) Image of an area of an abandoned cemetery showing three investigators looking toward unmarked grave of interest in missing persons investigation (arrow)

Geophysical/Remote Sensing Technology and Applications

This category is dedicated to every investigator who has ever said or thought, “I wish I had X-Ray vision.” In the development of search technology, the area of subsurface reconnaissance is one of increasing refinement and new developments. Perhaps, one day, researchers will come upon the X-Ray vision of science fiction or cartoons. For now, geophysical prospecting is limited to the identification of subsurface anomalies using variations in electromagnetic wavelengths. The only means of precisely determining the nature or cause of those anomalies is through excavation.

Subsurface reconnaissance methods may be divided, as Killam (1990) does, into six types: non-intrusive searches, intrusive ground searches, passive geophysical prospecting, active geophysical prospecting, remote sensing, and aerial photography. Resources on topics of non-intrusive searches, intrusive ground searches, and photography (see **Reconnaissance, Surveys, and Mapping Techniques, Photography, and Canines**), including more primitive search methods such as probing or coring, and materials on infrared and ultraviolet aerial photography could also have been included in this category in as much as they are among the defined search methods for subterranean anomalies. The compiler reserved this category, however, for those more sophisticated applications of physics and engineering which generally require consultation with certified engineers or archaeologists trained in geophysics. The references listed below are available for investigators who wish to consult with geophysical experts on the most appropriate means of applying particular techniques to particular settings. Such consultation should include an understanding of the techniques available, their potential given the unique parameters of each search area, and their limitations given those same crime scene conditions. Some engineering firms have experience in the application of their techniques to forensic settings. For the most part, however, the geophysical or structural engineer has never participated in forensic searches for buried evidence. Therefore, it is incumbent upon the investigator to understand how the techniques might be applied, as well as the basis for data generated from such applications. Like the use of cadaver dogs, aerial photographs, and other search techniques, the tool used in the search is often less important than its operator or handler. For example, the compiler has experienced searches using

ground penetrating radar in which the operators were able to run the equipment but unable to recognize the signature of a clandestine pit containing human remains. And like the use of cadaver dogs or other specialists, the investigator must not be afraid to ask for documented experience of the specialist.

The advantage to each of these techniques is their ability to limit the size of the search area. Investigators are often faced with subject or victim properties which range from small residential lots to farms or ranches of hundreds of acres. Geophysical techniques are often recommended to efficiently examine large open fields or yards. Infrared Thermography can be used to examine several acres in minutes, from an elevated platform. Ground penetrating radar has been used in the examination of large areas covered by concrete slabs which were thought to conceal buried evidence. By identifying small anomalies beneath such surfaces, manpower and cost savings are experienced in only having to core or break through small sections rather than opening the entire slab.

Some of the resources in this category are antiquated given the rapid pace of technological development in the field. Like other sections, however, these earlier articles help to shed light on the history of the field, and might offer some older, but relatively less expensive alternatives to “State of the Art” techniques. The bibliography likewise includes search techniques which are still in development as applications in forensic scenes. For example, the use of hyperspectral imaging to remotely identify skeletal elements among forest or field floor litter is now in the forensic science literature (Alsberg and Rosvold [2014], and Edelman, et al. [2012]) . Or its application to identify soil and vegetation changes over clandestine graves (Snirer and Kalacska, 2014). Readers and researchers interested in this section of the bibliography might also find useful references in **Planning, Reconnaissance, Surveys and Mapping Techniques**.

This section is divided into the following categories:

Ground Penetrating Radar	0181
Infrared and Thermal Technologies	0199
Magnetometry and Metal Detection	0204
Remote Sensing Technologies	0220
Hyperspectral Imaging Technologies	0246
Miscellaneous Techniques and General Topics	0251

Older model of ground penetrating radar equipment used in search for clandestine grave

Ground Penetrating Radar

Perhaps the geophysical prospection tool most requested at buried evidence search sites has been ground penetrating radar. Unfortunately, it is also one of the least understood resulting in exaggerated expectations of what results it might produce. Like most of the techniques included in this section, ground penetrating radar, (gpr), is limited by the geology and hydrology of the search area, the appropriateness of the equipment, and the skill of the operator. The compiler has experienced technological shortcomings with each these aspects. My expectations when I first had gpr used in the location of a possible clandestine grave were that the images produced from the survey would show the clear outline of a buried body and grave in profile. I soon found that the radar images can be quite complicated with only subtle reflections of subsurface anomalies confused or combined with interference from roots, animal burrows, rocks, clay strata, et cetera. Determining the appropriate type of antenna is one influence on signal quality. Foremost, however, is the experience and skill of the gpr operator. The decision of what antennae to use because of the nature of the site and any information known about the depth or configuration of the clandestine burial is that of the operator. As with the application of any expertise, the gpr operator's experience with the identification of forensically significant sub-surface anomalies is critical. Geophysical engineers are typically employed in deep exploration for natural resources. When brought from that environment into the scene of a relatively minute, shallow forensic target, they could be out of their element and confused by the results of a near surface survey. This is yet another example of why it is so important it is for crime scene investigators to cross-train with academic or non-forensic experts. If done properly with well trained technicians, properly and recently calibrated equipment selected for the specific site, and under rigid protocols, gpr data can be combined with total station or scanned data, to create three dimensional sub- to super-terranean views of a scene.

Infrared and Thermal Technologies

The compiler was first introduced to Infrared Thermography, (IRT), in the search for a clandestine grave among legitimate, but unmarked, graves of a defunct cemetery. The technique identified several anomalies which proved to contain partial or whole interments but none containing the remains of the homicide victim. The survey was a good introduction to the capabilities of this type of technique in open areas. That was also the best demonstration of the limitations of IRT in forensic situations. The first being that the burial feature is easiest to identify in an open area rather than concealed by tree canopies or structures. Unfortunately, the criminal actor is most likely to choose an area which provides concealment rather than an open field. Another limitation was that best results occur after the scene has been prepared by mowing or cutting vegetation to a consistent height. Like all geophysical methods, infrared and thermal techniques are as successful as allowed by the sophistication of the equipment used and skill of those who interpret the collected data. Experience and knowledge of forensically analogous settings are the best means of accurately determining the differences between a possible clandestine grave and a large rodent burrow or the plume of an illegally buried and leaking waste site from natural subterranean hydrologic activity. The use of Forward Looking Infrared (FLIR), Push broom imaging, or other mounted thermal imaging systems, to detect living and decompositional heat signals above ground may not require as much training and experience as is necessary to realize the subtle reflected signals from radiant heat signatures of the disturbed area of a grave feature compared to the undisturbed matrices into which it was dug and infilled. The advantages of thermal imaging technology include the efficiency with which large areas can be covered from remote platforms. Combined with other techniques, IRT and other thermal technologies should be among the tools considered by crime scene searchers.

Magnetometry and Metal Detection

A relatively inexpensive search tool found in most crime scene vans is the metal detector. Ranging in sophistication and sensitivity, magnetometers can be used to locate metallic items such as ammunition components, weapons, or metal segments of clothing. Searchers should also explore the use of such equipment in locating burial features based on subtle changes in magnetism between disturbed and undisturbed fill. Similarly, burial features containing burned evidence may demonstrate characteristics which can be identified with the used of magnetometers. Magnetometry is not only limited to terrestrial applications. In more than one investigation, the compiler has requested the assistance of dive teams to search for weapons or other evidence allegedly thrown into bodies of water. Most recently, evidence associated with the murder and clandestine burial of a victim was located in a river two years after its disposal. For the crime scene investigator, or search personnel, the difference between magnetometry and metal detection lies in their intended applications. Magnetometers measure the intensity of the earth's magnetic field as influenced by above, or below, ground interferences such as buried metal objects or overhead power lines, metal fences, et cetera. They only respond to ferrous metal, but can do so to much deeper depths than metal detectors. Magnetometers can be mounted to vehicles to cover large areas. Both techniques may require data processing software to extract relevant data from complex settings such as buried strata with high ferrous content. Metal detectors respond to ferrous and non-ferrous metals at relatively shallow depths. The signals of both techniques require, again, experience and training to interpret sometimes subtle signals of targeted objects. (315 citations)

Hyperspectral Imaging Technologies

One type of remote sensing has its own category in the bibliography because of its continued development toward forensic applications including the location of clandestine graves (Leblanc, Kalacska, and Soffer, [2014]). Hyperspectral imaging has also been used in evidence analyses such as blood stain examinations (Edelman and Aalders, [2015]), and document examination, (Goltz, et al., [2010]). Hyperspectral imaging was originally developed for mineral and oil prospection. Soon its applicability to agricultural crop monitoring was realized and, more recently, forensic applications have been considered. In the picture above, polarimetric shortwave infrared hyperspectral imaging was used to detect and distinguish properties of disturbed soil, vegetative growth, and decompositional gases (Tobin, 2014).

Hyperspectral and multispectral imaging are sometimes confused. The difference is in the number, and width, of bands which can be detected along the electromagnetic spectrum of infrared, visible, and ultraviolet radiation. Hyperspectral imaging detects hundreds of thousands of bands using an imaging spectrometer while multispectral technology senses three to ten bands using a radiometer. As such, hyperspectral imaging has more capability to collect spectral data for each pixel captured by a sensor and therefore better opportunity to locate objects, identify the makeup of matrices, as well as the processes which affect(ed) those objects or matrices. Miscellaneous Techniques and General Topics

In this subcategory, geophysical and remote sensing processes which may not be as common as those cited above, (ie. seismology, electrical resistivity, gravity, or gradiometry), can be found. Also included are those references which generally refer to multiple technologies; or sites surveyed with multiple geophysical methods. As mentioned throughout this section of the Bibliography, the quality of the equipment and user are paramount to the success of any given technique.

The initial stages of a forensic excavation removing the top horizons within a delineated area in search for a pit feature

Excavation and Recovery Strategies

Regardless of the search method which brings the investigator to a site believed to contain buried evidence, there is only one means, to date, of precisely determining what that spot contains. In making that determination, it is as important to recover and document the precise position of associated and trace evidence as it is the primary piece of evidence. It has been the compiler's observation that law enforcement examinations of buried body crime scenes, in particular, tend to concentrate on the location and removal of the primary evidence - the body without consideration of those archaeological (geotaphonomic) features which explain its context. There is considerably less "excitement", and therefore emphasis, on associated and trace elements. This can be extremely unfortunate given the value of such evidence in determining when, why, how, and by whom the body was deposited. The effects of time and environment on the post-depositional history of remains represent the bases of taphonomy. The lack of similar emphasis on recognizing and collecting associated and trace evidence caused the compiler to consider geotaphonomy as a legitimate area of research in forensic science.

Geotaphonomy is defined as the study of the geophysical characteristics of, and changes in, surface to subterranean features associated with the interment of buried evidence. The concept of forensic geotaphonomy developed out of a realization that investigators of clandestine graves, or other buried evidence crime scenes, lacked precedent demonstrating the possible geophysical features or conditions which could aid interpreting subterranean scenes. Although they are seldom noticed at contemporary crime scenes, many of these conditions are the bases of archaeological tenets. In geotaphonomy the features comprise six areas or classes of evidence which are introduced

during and after the original excavation and backfilling of subterranean pits. The six classes of geophysical evidence include stratification, tool marks, bioturbation, sedimentation, compression/depression, and internal compaction.

In order to record the context of buried evidence, it is paramount that proper archaeological excavation techniques be applied. Often, what is described in media accounts as “archaeological excavation” for the remains of a homicide victim, are in fact merely “digging up” the remains. For the recovery to truly be archaeological, two immutable principles must be followed: the excavation must be systematic, and it must include the recognition and documentation of all contextual, or environmental, artifacts. Toward providing resources which describe, affect, and/or suggest methods in archaeology, the following citations were compiled. Included are a few specific site reports with which the compiler had access or was aware. It should be understood that thousands of such reports are prepared by academic and engineering institutions around the world. They continue to be drafted as sites of historical and archaeological significance are excavated. It would not be feasible to include even a fraction of these reports. What becomes readily apparent after a review of the following citations is the diversity of search settings, and the need to form equally diverse plans toward the excavation of these sites. As long as the principles of systematic excavation and contextual recovery are maintained, flexible excavation strategies will remain appropriate. The archaeologist receives training in soil and botanical sciences in order to understand the formation processes of those matrices into which cultural features intrude. For that reason the reader or researcher is also referred to the categories of **Geoarchaeology and Soil Science**, as well as **Botany and Related Areas**.

Potential sources of forensically significant soil samples

Geoarchaeology and Soil Science

Geological and pedological processes of formation affect the ante-, peri-, and post-deposition of artifacts or evidence. Areas of geotaphonomy such as Stratification, Bioturbation, Compression/Depression, and Sedimentation are fundamentals of geology. An understanding of geological, pedological and hydrological processes must extend beyond the immediate crime scene feature to the surrounding environment. For example, information that a victim's body was buried near a river ten years ago, is greatly supplemented with an understanding of the effects of soil formation, erosion, and hydraulics in a flood plain environment. The compiler encountered one such scene along the Mississippi River. After a man fishing discovered a skull and other human skeletal elements scattered across an embankment along the river, he reported the find to the local Sheriff. The systematic recovery, and three dimensional documentation of same, illustrated a pattern of distribution in which the remains were carried down the embankment in the direction of waves that slapped against the shore. As the shore eroded over the years, it exposed and disrupted a historic burial along the river cove. Archaeologically, the distribution of cut iron nails further supported the interpretation of the scene as an eroded historical grave.

Remote sensing and photogrammetric data of topographic, geological, and botanical conditions can be used to reconstruct a history of the search or crime scene environs (See **Geophysical/ Remote Sensing Technology and Applications** .) Although every site will be unique, there are basic principles of stratification, superposition, and contemporaneous deposition, which have served as tenets of geology and archaeology since the seventeenth century. The impact of burrowing animals, and even earthworms, (Bioturbation), on buried objects is well documented. An awareness of the terrestrial and subterranean fauna inhabiting crime scene environs may be essential in understanding the formation and or disruption of soils containing primary, associated, and trace evidence. For this reason the reader is directed to "**Reconnaissance, Surveys, and Mapping Techniques**" for general guides to the types of fauna which might inhabit a particular crime scene area. Likewise, the subsection of "Scavenging" within the section on "**Taphonomy**" contains references to subterranean animals which directly impact buried evidence and the subterranean feature in which they are contained.

This subsection contains references directly and indirectly addressing soil sciences including the recognition and interpretation of soils in archaeological contexts - geoarchaeology. Of interest, from the standpoint of trace evidence, are those references to cases in which geoarchaeology has been utilized not only to understanding soil

formation/alteration related to buried evidence, but in identifying once buried items via trace soil evidence (ie. Adovasio, et al. [1991]). It has been the experience of the compiler that forensic scientists are generally unfamiliar with work accomplished on, and toward the interpretation of, traditional archaeological sites. Most forensic references in forensic geology concentrate on laboratory techniques and analyses, rather than formal archaeological collection of geological and pedological samples/evidence. Therefore, this section occasionally references archaeological site reports, or journal articles, citing specific site interpretations and the techniques used in those interpretations. The reader is also referred to sections such as **Stable Isotope Analyses** and **Shoe, Foot, and Tire Impression Evidence**. in as much as soil sampling is necessary for control and comparative purposes.

Scavenged human remains in a naturally eroded depression

Taphonomy

Taphonomy has been defined as the study of the processes by which animal and plant remains become fossilized. The discipline arose from the work of paleontologists to explain the contexts and conditions of fossilized remains. Taphonomy, with its roots in the Greek “taphos” for tomb or burial, and “nomos”-laws, was adapted by physical anthropologists to explain, and sometimes predict, the condition and contexts of more recent and often forensically significant finds. In this respect, and especially as it applies to forensic situations, taphonomy has come generally to refer to the science of examining transitions of remains from the biosphere to the lithosphere as impacted by weather, animals, plants, biochemical reactions, and cultural factors. Marin-Arroyo, et al. (2012), Dirkmaat (2013), and Borrini and Tomba (2014), serve as some of the most recent works discussing the various forms those transitions might entail. They represent three of many sources, offered below, which demonstrate the multitude of areas currently being researched to explain reasons for, and the results of, particular transitional events. Taphonomy includes various agents of bone modification, but is not limited to that alone. Soft tissue transitions occur as do those to hair, nails, wound and other defects.

The general Taphonomy section has been broken into individual sections for topics of "**Decomposition and Time Since Death**", "**Disease, Illness, and Physical Abnormalities**", "**Thermal Alterations and Influences**", "**Scavenging, Animal Attacks, Faunal Turbation, and Bitemark Evidence**", "**Trauma**" and "**General or Miscellaneous Topics**". References in each of these sections may be related to other sections of the bibliography. For example, the topic of wounds comprise part of the taphonomic record on a body or its remains. As a result, one of the largest subsections under Taphonomy is devoted to sharp, blunt, ballistic and other traumas. Researchers interested in this subarea of taphonomy should also search **Firearms and Toolmark Evidence** in as much as resources on terminal ballistics or wound ballistics may be included in that section of this bibliography. Another example may include the relationship between bite marks and criminal behavior. As taphonomists, physical

anthropologists are interested in both skeletal and soft tissue injuries, as well as changes to those matrices and their injuries over time. One form of taphonomic change which takes place over time is decomposition. Whether it be the formation of adipocere, diagenesis of bone, or cremation as a form of further concealment, the condition of tissues can reflect changes in environment and/or the length of time since disposal. In almost every environment where remains are disposed or concealed, animals, large and small, feed or otherwise scavenge decomposing tissue. Such modifications are addressed in a subsection on scavenging. Modifications of interest to anthropologists and pathologists can also be caused by feeding insects, to which they are referred to the section on **Entomology**. Another large grouping of references in this category consist of those about diseases and illness. The antemortem health of victims as reflected in their remains is as important for the forensic investigator as reflections of peri-and postmortem circumstances. Certain conditions such as bone diseases, broken bones, or the use of prosthetics, can aid investigators in identifying victims or reconstructing a victim's ability to perform certain actions associated with their deaths or disappearance.

Because of taphonomy's roots in paleontology, many of the resources in this section deal exclusively with paleontological theory and method. Prehistoric archaeological examples of taphonomy also constitute several citations. It is important for researchers to understand the bases for theories and methodologies which have come to be applied in forensic settings. Just as traditional physical anthropology and archaeology drew upon the earlier works of paleontologists, much current work in forensic taphonomy relies upon discoveries made during the exhumation of historic and prehistoric burials. The reader is referred back to the section on "**Excavation and Recovery Strategies**" for additional archaeological site reports which may contain taphonomy related information. Likewise, "**General Crime Scene and Death Scene Investigation**" may contain research regarding wound or trauma analysis and pathology - topics which are inherently taphonomic. From wound, (or terminal), ballistics to transitional, or (external), ballistics and ultimately to initial, (or internal), ballistics, the taphonomic record of gunshot wounds is linked to the examination of firearms and ammunition. Readers interested in resources related to gunshot wounds should also refer to the category of **Firearms and Toolmark Evidence**. Additionally categories such as **Mass Fatality and Human Rights Investigations** should be reviewed for references which contain details of site environments, (ie: mass graves, building collapses), or manners of death, (ie: torture, post-blast, or crash conditions), which impact the taphonomy of remains.

Desiccated remains of an individual found in an abandoned apartment approximately nine months following his death

Taphonomy – Decomposition and Time Since Death

Paramount in any criminal investigation is the chronology of incidents throughout the criminal event. Likewise, any death

investigation seeks to determine when the decedent passed. It is from that point in time that investigators direct their interviews, examinations, and interpretation, to determine the actors and places involved in the event. The postmortem interval or "PMI" can be affected by temperature, environment, insects, animals, and plants. Each of those taphonomic agents have a dedicated section or subsection within this Bibliography. (2237 citations)
